Conclusion

Problem Statement

The problem statement of this project has been taken from the following website:

CS663: Digital Image Processing

We have built an image compression engine along the lines of the JPEG algorithm. Along with this, we have implemented PCA (both for coloured and grayscale images) algorithm. We have thoroughly studied a tier-1 conference paper Edge-Based Image Compression with Homogeneous Diffusion and implemented the algorithm proposed in the paper.

All the algorithms were tested on a variety of image datasets. The results were compared and analyzed to understand the performance of the algorithms.

Problem Statement

Basic Implementation

Here are the steps which were performed as part of the basic implementation:

- Computation of the 2D DCT coefficients of non-overlapping image patches
- Implementation of the quantization step
- Implementation of the Huffman tree
- Writing data to an appropriate file format (.bin) and plotting RRMSE vs BPP

Here is the expression of RMSE:

$$\mathsf{RMSE} = \frac{\sqrt{\frac{1}{N} \sum_{i=1}^{N} \sum_{j=1}^{M} (I_{\mathsf{orig}}(i)(j) - I_{\mathsf{recon}}(i)(j))^2}}{\sqrt{\frac{1}{N} \sum_{i=1}^{N} \sum_{j=1}^{M} (I_{\mathsf{orig}}(i)(j))^2}}$$
(1)

where I_{orig} is the original image and I_{recon} is the reconstructed image. BPP stands for the size of the image in bits divided by the number of pixels.

RMSE vs BPP

For the basic implementation, we have used the dataset from the miscellaneous category of the msrcorid dataset. We picked random 20 images and used 20 quality factors (in the range of 1 to 100) to plot the RMSE vs BPP graph. Here is the graph:

Run Length Encoding

The quantized DCT coefficients are arranged in a zigzag order. This pattern leaves a bunch of consecutive zeros at the end.

In runlength encoding, we replace the consecutive zeros with a pair of numbers: the number of zeros and the value of the next non-zero element. This reduces the size of the data to be stored.

PCA on a Single Grayscale Image

- Pad the image suitably to make dimensions a multiple of 8.
- Divide the image into patches of size 8×8 and flatten them into column vectors
- Compute the column correlation and row correlation matrices of the matrix of flattened patches.
- Compute the kronecker product of the two matrices and extract eigenvectors of this matrix with the top k eigenvalues. These eigenvectors are the principal components.
- Now project the original image onto the column space of these eigenvectors. The resulting matrix is the compressed image.
- Reconstruct the image by multiplying the compressed image with the transpose of the eigenvectors.

Principal Component Analysis

PCA on a Dataset of Grayscale Images

- Pad the images suitably to make dimensions a multiple of 8.
- Divide each image into patches of size 8×8 and flatten them into column vectors. Create a matrix whose columns are the flattened image patches.
- Compute the column correlation and row correlation matrices of the matrix of flattened patches.
- Compute the kronecker product of the two matrices and extract eigenvectors of this matrix with the top k eigenvalues. These eigenvectors are the principal components.
- Now project each of the original images onto the column space of these eigenvectors. The resulting matrix is the compressed image.
- Reconstruct any image by multiplying the compressed image with the transpose of the eigenvectors.

PCA on a Single Coloured Image

- Pad the image the suitably to make dimensions a multiple of 8.
- Treat each image channel as a grayscale image and run the PCA algorithm on each channel separately.
- Extract the compressed image for each channel separately and merge them to get the compressed coloured image.
- Reconstruct the image by multiplying the compressed image of each channel with the transpose of the eigenvectors of that channel.
- Merge the reconstructed channels to get the reconstructed coloured image.

Edge-Based Image Compression

This paper is based on the fact that edges contain semantically important information in an image. They present a lossy compression method for cartoon-like images.

Conclusion

Encoding Steps

- Firstly, we need to detect edges in the image. The paper proposes Marr-Hildreth edge detector. However, based on our initial experiments, we found that the Canny edge detector works better.
- Now we store the result of edge detection using JBIG(Joint Bi-level Image Experts Group) encoding.
- Then, we encode the contour pixel values. Basically, we store the values from both sides of the edge. The extracted pixel values can be uniformly quantised to 2^q different values, where $q \in \{1, 2, \dots, 8\}$. Another parameter d, ensures that only every d^{th} value along an edge is stored.
- The quantised and subsampled pixel value signal is then compressed by a PAQ compression method (lossless compression archiver).
- Now, we need to store the encoded data along with all the values of the hyper-parameters.

Paper Implementation

Decoding Steps

- We split our encoded file into the JBIG data and PAQ data part.
- Both parts are then decoded by using the JBIG and the PAQ method, respectively.
- We reconstruct the quantised colours obtained by the PAQ part.
 The pixel values between the sampled points are computed by using linear interpolation along each edge.
- The JBIG data provides a bi-level edge image of the original image size. Given the image size and the edge pixel positions, the pixel values are arranged around the edges in the same order in which they have been encoded.
- Now, we have decoded the edge locations and the pixel values surrounding the edges. We use diffusion based inpainting to fill the remaining values.
